ACKNOWLEDGEMENTS

We thank Bob Summerfield and Nancy Warren for their help throughout the study. We were assisted with field work by Eric Atkinson, Stan Beckstrom, and Chad Castren. Additional help, location of possible trapping sites, and other logistical support was provided by J. Ashley, D. Boots, J. Davies, S. Gniadek, C.E. Hidy, C. Jones, F.B. Sanchez, and other Forest Service and Park Service personnel. C. Jones and C. Craig assisted with element occurrence and map preparation. Financial support for the project came from the Kootenai and Flathead National Forests (U.S. Forest Service, Northern Region) and the Montana Natural Heritage Program (The Nature Conservancy).

INTRODUCTION

The harlequin duck (Histrionicus histrionicus) is a small sea duck, found inland only during the breeding season. The male is strikingly colored with black and white spots and slashes, and chestnut sides on a deep cobalt blue background. The female is dull brown with three white spots on her face. Harlequins breed in western North America from Alaska and the Yukon south through western Montana to California; in eastern North America they breed form Baffin Island south to eastern Quebec and Labrador (Goudie 1993). In the Palaearctic they breed in Iceland, Greenland and Siberia (A.O.U. 1983). Approximately 110 pairs of harlequins currently breed in Montana (Genter 1993), with most located in the following areas: 1) tributaries of the lower Clark Fork River; 2) tributaries of the North, Middle, and South Forks of the Flathead River; 3) streams coming off the east front of the Rocky Mountains; and 4) the Boulder River (Miller 1988, 1989, Kerr 1989, Carlson 1990, Fairman and Miller 1990, Diamond and Finnegan 1992).

During the breeding season harlequins are found along fast mountain streams (Bengston 1966). In many areas harlequins use streams with dense timber or shrubs on the banks (Cassirer and Groves 1990), but they are also found in relatively open streams along the east slopes of the Rocky Mountains, Montana (Markum and Genter 1990, Diamond and Finnegan 1992) and the Arctic tundra (Bengston 1972). In Idaho, 90% of observations occurred near old growth or mature timber stands (Cassirer and Groves 1990). Mid-

stream rocks, logs, islands, or stream-side gravel bars serve as safe loafing sites are important habitat components.

Most of the ducks arrive on their inland breeding areas in mid-April to early-May; unmated males typically arrive before pairs (Kuchel 1977). The males return to the coast shortly after the females begin incubation; most are gone by early July (Kuchel 1977). The females and young remain on the streams until August or early September. This chronology is influenced by elevation and the timing of spring runoff and may vary up to several weeks between years.

The U.S. Forest Service, Region 1, lists the harlequin duck as Sensitive (Reel at al. 1989). The species is listed as a Species of Special Concern by the Montana (Genter 1992) and Idaho (Moseley and Groves 1990) Natural Heritage Programs. The eastern North American population is listed as endangered in Canada (Goudie 1993); the western population is listed under Category 2 as a candidate for listing under the Endangered Species Act by the U.S. Fish and Wildlife Service (U.S. Department of Interior 1991).

The Montana Natural Heritage Program began surveying harlequin ducks in 1988. The survey data gave rise to questions involving site fidelity, productivity and mortality. Individual marking of birds began to a limited extent in 1991. Long term goals are: 1) developing a baseline status report of current and historic harlequin populations in Montana; 2) gather information on site fidelity, reproduction and mortality to allow estimations

of what constitute viable harlequin populations; 3) develop surveying protocols for actual and potential harlequin streams; 4) develop management guidelines for maintaining and restoring harlequin populations and habitat. Goals for 1992 included: 1) surveying additional streams for presence and status of harlequins; 2) gathering productivity data on some primary harlequin streams; and 3) marking as many individuals as possible on selected streams for long-term monitoring.

METHODS AND MATERIALS

Harlequin ducks were surveyed on parts of the Kootenai, Flathead and Lolo National Forests during May-August 1992. Most surveys were conducted by walking the stream channel (when possible) or stream bank. In most cases the surveyor walked upstream, giving more time to observe the bird before it moved out of sight. Some large streams on the Flathead National Forest were surveyed by kayak or raft. Dates, locations, km surveyed, and general characteristics of the stream reaches surveyed were recorded; any harlequins sighted were noted with location, numbers, ages, and sex of birds present. For several streams in the Flathead and Clark Fork drainages, we attempted to capture and mark all birds seen, when a licensed, qualified birdbander was present on the survey. Captured birds were identified to sex and age, weighed, measured (wing and tail), marked, and released. Except in Glacier National Park, all birds were marked with numbered USFWS aluminum leg bands and colored nasal discs, individually

recognizable by shape and color combinations. The Park felt the nasal discs would be aesthetically unacceptable to Park visitors. Birds in Glacier National Park were banded with USFWS bands and a unique combination of 3 plastic, colored leg bands.

RESULTS AND DISCUSSION

Surveys

Flathead National Forest. Pair surveys were conducted along 200 km of 12 streams during May-June 1992 (Table 1). A minimum of 13 harlequins (5 males, 8 females) were seen on 3 streams (Table 1, Appendix B & C). These included the North Fork of the Flathead River (1♂, 2♀), Sullivan Creek (2♀), and Trail Creek (4 pairs); additionally we had reports of harlequins from the Middle Fork of the Flathead River (1♂ and 1 pair; H. Rivera) and Harrison Creek (1♂; J. Graham) (Table 2).

Brood surveys were conducted along 301 km of 22 streams during July - August 1992 (Table 1). A minimum of 43 different harlequin ducks were observed on 6 streams (Table 1, Appendix B & C). These included: 1) Little Salmon Creek (2♀, 2 brood w/ 3 & 5 young), 2) South Fork of the Flathead River (4♀), 3) Spotted Bear River (1♀, 2 broods of 3 & 4 young), 4) Sullivan Creek (2 birds, either adult ♀, or fledged young), 5) Trail Creek (2♀, 2 broods of 4 & 4 young), and 6) White River (3♀, 3 broods of 1, 2, & 3 young). Additionally S. Sigler reported birds on the Middle Fork of the Flathead River (3♀, 2 broods of 5 & 4).

No harlequins were observed on Bunker Creek, Mid Creek, Big

Creek and Wounded Buck Creek where they have been observed in at least one of the past five years.

Kootenai National Forest. Pair surveys were conducted along 36 km of 3 streams during May-June 1992 (Table 1). A minimum of 8 harlequins (5 males, 3 females) were seen on 2 streams (Appendix B & C). These included the Vermillion River (1♂, 1♀) and Marten Creek (2 pairs plus 2♂).

Brood surveys were conducted along 41 km of 5 streams during late July - August 1992 (Table 1). A minimum of 18 different harlequin ducks were observed on 1 stream (Table 1, Appendix B & C). Marten Creek had 5♀ present with 4 broods (4,4,4,1).

No harlequins were observed on Rock Creek, Elk Creek and Swamp Creek where they have been observed in at least one of the past five years.

Lolo National Forest. Brood surveys were conducted along 42 km of 3 streams during August 1992 (Table 1). Three different harlequin ducks were observed on 1 stream (Table 1, Appendix B & C). The North Fork of the Blackfoot River had 3 juveniles present. Additionally an angler we talked to on the bay at the mouth of Marten Creek (Kootenai NF), reported that he had seen a female with a small brood in July on Graves Creek; he also stated he had seen harlequins on Deep Creek in previous years, but not in 1992. He was able to tell harlequins from other ducks present at the time (mallards and common mergansers). However, our survey and past surveys on Graves Creek have failed to find harlequins (Miller 1989, Fairman and Miller 1990). No harlequins

were observed during a survey of Trout Creek where they have been observed in at least one of the past five years.

Glacier National Park. Brood surveys were conducted along 24 km of the McDonald Creek drainage on 10-11 August 1992 and along 16 km again on 2 September 1992 (Table 1). A minimum of 50 different harlequin ducks (12♀; 13-14 broods of 1, 1, 2, 2, 3, 3, 3, 4, 4, 4, 7, and a group of 8 young with two size classes present) were observed on McDonald Creek and an additional 3 (1♀ with 2 young) on Mineral Creek (Table 1, Appendix B & C). Many other surveys were conducted throughout the season by Glacier National Park personnel (Ashley 1992). These surveys found considerable mixing of broods, both before and after marking on 10-11 August.

Breeding Chronology and Effects on Surveying. Breeding was very early this year, probably due to very low flows during spring runoff. As a result, most females apparently began egg laying and incubation several weeks early; males had left by the second pair survey of Marten Creek on 1 June. The last male was seen on McDonald Creek on 23 June 1992 about 10 days earlier than reported in 1973-75 (Kuchel 1977, Ashley 1992). All young were fledged or nearly flying by 4 August on Marten Creek and 12 August on Trail Creek. Some females and young left Marten Creek by 7 August. If other streams surveyed were more advanced chronologically, birds might have already left for the coast by the time the streams were surveyed for broods. However, most females and young were still present on 11 August at McDonald

Creek in Glacier National Park, and over 50% still remained on 2 September (Table 1). Surveys on Red Meadow, Rock and Swamp creeks were most likely to have been affected, since many reaches had extremely low flows or were intermittently dry by early August.

Reproduction

Harlequins were present this year on at least 12 streams in the study area and adult females or broods were seen on 11 of those streams. A minimum of 42 adult females were present. Of 42 potential broods, a minimum of 31 were produced for a 74% success rate of broods per adult female. Mid-late August brood size averaged 3.27 (n=30). Most broods were seen in Class III or fledged stages of development (Bellrose 1976:27), and we made no adjustment for age of broods in our calculation of mean brood size. Success rates per adult female are biased by having incomplete early pair surveys for comparison on some streams, resulting in high recorded success rates. However, this may have been offset by some broods fledging and leaving the area prior to brood survey completion on some streams such as Trail Creek and the Vermillion River.

Capture and Marking

The first year of the juvenile Harlequin Duck site fidelity and survival study got off to a good start. A total of 62 juvenile birds from 4 drainages were captured and marked (Table 3, Appendix D & E). Five adult males and 18 adult females were marked in addition to the 4 males and 2 females marked in 1991 (Table 3, Appendix D & E).

The two females and one male marked with nasal disks on Marten Creek in 1991 were recaptured in 1992. No problems with the nasal disks were apparent. The ducks appeared healthy and each female successfully raised broods of 4 young during 1992.

However, USFWS aluminum leg bands were moderately worn on one female and severely worn on the other (the last number was nearly illegible). Additionally, one of the females had apparently been shot, probably in the fall 1991 hunting season; several healed, round, shot-sized holes were present in the foot webbing.

While banding in Glacier National Park in August we noted that some birds had tarsi too short to safely use both a plastic leg band and USFWS band on the same leg. In those cases we split the plastic band to make it only 1/2 as tall. This appeared to work well on one bird recaptured in September. However, we did note some injury to the hallux on both legs on another recaptured bird where all bands were full height. We used one split band (top) and one whole band (bottom) on all subsequent birds banded. We recommend that all birds banded in the future have the upper color band split in half to prevent this problem from reoccurring.

TOTAL	9	20	(4)	62	91

MANAGEMENT RECOMMENDATIONS AND RESEARCH NEEDS

Adult harlequins show strong fidelity to breeding sites (Bengston 1972, Kuchel 1977, Dzinbal 1982, Wallen 1987). The extent of fidelity to natal areas by adults breeding for the first time is unknown, but is likely to be strong. Colonization of currently unoccupied streams is likely to be a rare event. Harlequins appear sensitive to human disturbance (Clarkson 1992, Cassirer and Groves 1991). Repeated disturbances may discourage nesting at traditional sites and reduce productivity (Rodrick and Milner 1991). However, proximity to trails and roads does not always correlate with reduced reproductive success. Sixty percent of harlequin sites were within 50 m of trails on the Rocky Mountain Front (Diamond and Finnegan 1992). In this case, most harlequin streams are located in roadless or wilderness areas and receive limited human activity prior to or during the nesting period.

Mid-stream loafing sites are important in breeding areas (Cassirer and Groves 1990). Brood rearing areas in Idaho and Montana west of the Continental Divide have a dense shrub or timber/shrub mosaic on the banks (Cassirer and Groves 1989, Gangemi 1991). East of the Divide in Montana stream banks are more open, and most observation sites had banks composed of gravel, grass-forb, or bedrock habitat (Diamond and Finnegan 1992, Markum and Genter 1990). Low benthic macroinvertebrate biomass may limit the number and productivity of harlequins (Bengston and Ulfstrand 1971, Kuchel 1977). Given these factors, we recommend the following management strategies on harlequin streams:

1) minimize unnecessary human activity along harlequin streams during May through August (mid-May through June is the critical nesting period when birds are most sensitive);
2) a stream buffer of > 50 m should be maintained on both sides of streams for most activities; roads and trails should be > 100 m from streams and not visible from the streams;
3) major activities (road building, timber harvest, restoration projects, etc.) that are to be undertaken within 300 m of a stream should be done during the period 15 August - 1 April;
4) minor activities within stream buffers (e.g. trail maintenance or reconstruction) should not be preformed during 1 June - 15 July;
5) avoid activities which will change stream runoff patterns or decrease water quality;
6) limit access to harlequin streams during the breeding period May - August; in particular do not promote activities which will bring people into contact with harlequins; and
7) in any area where major management activities are to take place in potential harlequin habitat, survey for the preceding two years both for pairs (May) and broods (mid-July to mid-August). If harlequins are present, develop a monitoring plan for harlequins during and after the activity is to take place.

Long term research and management needs involve:

1) develop a baseline status report of current and historic

harlequin populations in Montana (currently in preparation);

2) investigate site fidelity, inter-stream movement, reproduction and mortality to allow estimations and modeling of what constitutes a viable harlequin population (began in 1992);

3) determining the primary limiting factors for harlequin duck populations in occupied and historic habitat situations in the Northern Rockies;

4) developing standardized surveying protocols for occupied and potential harlequin streams;

5) developing management guidelines for maintaining harlequin populations and habitat; and

6) assess the impacts of past and current habitat modification and develop techniques to restore harlequin populations and habitat.

Size (acres): 60

Location:
UPPER MCDONALD CREEK IN GLACIER NP; STREAM SECTION FROM CONTINENTAL CREEK SW TO THE NORTH END OF LAKE MCDONALD, AND INCLUDING MINERAL CREEK AND AVALANCHE CREEK AND LAKE.

Element occurrence data:
A POPULATION OF HARLEQUIN DUCKS WAS STUDIED OVER 4 YEARS. 31 BIRDS, INCLUDING 7 JUVENILES, WERE BANDED. 11-14 PAIRS PRESENT. 6/5/90: 4 PR, 11 MALE, 3 FEMALE PRESENT. 1992: A MINIMUM OF 14 BROODS PRODUCED A TOTAL OF 45 YOUNG; COLOR BANDED 40 YG AND 13 ADULT FEMALES.

General site description:
CA. 20 MILES OF MOUNTAIN STREAM.

Land owner/manager:
GLACIER NATIONAL PARK

Comments:
EXTENT OF OCCUPIED BREEDING HABITAT UNKNOWN. SPRING PAIRS AND LATE SEASON YOUNG REPORTED ON LOWER MCDONALD CREEK MAY OR MAY NOT BE BIRDS FROM UPPER MCDONALD CREEK POPULATION.
